## OBJECTIVE

The aim is to simulate the go-back-N ARQ flow control protocol between processes using socket programming.

## DISCUSSION

- The socket server and client are realized using the same socket library in the second experiment.
- The propagation delays across the channel are modeled by introducing a delay between receiving a data packet and sending an acknowledgment.
- Loss of data packets due to errors in the channel is modeled by sending a NACK instead of an ACK with a small probability, which is the probability of error of the channel.
- A large probability of error results in a higher number of NACKs being sent, which in turn reduces the data rate.
- The receiver, which is the server, has to be run first followed by the sender, which is the client. Else the client would terminate as the server is not reachable. The code continues to run until the sender transmits all the data.
- End of data transmission is indicated by sending a newline character `\n`.
- Stop-and-wait protocol is a special case of go-back-N where the value of N is 1.

## CODE EXPLANATION

This section gives a brief overview of the code present in `send.cpp` and `recv.cpp`.

### Sender:

- The `sender` has a vector containing the data to be sent, whose last element is `\n`.
- An instantiation of the `SocketClient` object is used to send the data.
- The sender sends N data packets and waits for N ACKs.
- The `sentDataIndex` and `recvDataIndex` variables keep track of what data is to be sent and how many ACKs have been received.
- The `recvDataIndex` is incremented if an ACK is received, and the `sentDataIndex` is assigned the value of `recvDataIndex` if a NACK is received.

## Receiver:

- An instantiation of the `SocketServer` object is used to receive the data.
- The receiver receives N data packets and generates a random number to decide whether to send an ACK or a NACK and adds them to a queue.
- It stores the received data in a vector if an ACK is to be sent.
- It sends all the queued acknowledgments once N data packets are received.
- The receiver stops receiving if it successfully receives a `\n`.

## RESULTS

The sender-side:

```
sanjeet (main *) bin $ ./send
CLIENT INFO: Connected to 127.0.0.1
1 Two
2 plus
3 two
4 is
5 four
TIMEOUT: Packet 0 ACK not received, resending last packet!
1 Two
2 plus
3 two
4 is
5 four
Packet 0 ACK Received: Sending next data packet!
Packet 1 ACK Received: Sending next data packet!
Packet 2 ACK Received: Sending next data packet!
Packet 3 ACK Received: Sending next data packet!
Packet 4 ACK Received: Sending next data packet!
6 minus
7 one
8 that's
9 three
10 quick
```

The receiver-side:

```
sanjeet (main *) bin $ ./recv
SERVER INFO: Listening for connections!
NACK
Two
plus
two
is
four
minus
one
that's
three
quick
```

## CONCLUSION

- The go-back-N ARQ flow control protocol is implemented.
- The Socket library written in the second experiment is used to create the socket server and client.
